**INSTRUCTIONS FOR THE ASSEMBLY OF THE MACHINE STAND      Group A**

**Before you start the assembly arrange the individual parts of Groups A, B and C.**

**Start the assembly with Group A, by placing Part 1 against the Parts 2 and 3, and inside Part 4, and screw them together with the respective nuts and bolts.**

**To begin with the screws are not to be tightened.**

**Group B**

The assembly of Group B is carried out in the same way as Group A, i.e. Part 1 is placed against the Parts 5 and 6, and Part 4 inside. Then they are screwed together with the respective nuts and bolts.

Group C

Now Group C is connected and screwed together with the two Groups A and B. All screws of the machine stand can now be tightened. Doing this, it is important to make sure that the stand rests evenly on the ground.

If now the EMCO-REX B 20 is mounted on the machine stand, the following has to be observed:

The machine has to be placed on to the stand in such a way that the handle which is used for adjusting the surfacing part is on the side of the two castors.

Now the 4 bolts (M8x25 DIN 931) are entered into the bores from above and tightened with the nuts (M8 DIN 934) and the washers (8.4 DIN 125). The machine can be moved about by lifting it at the opposite side of the handle mentioned above.

### MOUNTING DIMENSIONS FOR A SELF-BUILT TABLE FOR EMCO - REX B 20

If our machine base Order Ref. 6260 was not ordered with the EMCO - REX B 20, a table with the following mounting dimensions has to be built (see Diagram):

The minimum size of the table top would have to be 410 x 390 x 24 mm (approx. 16 1/8 x 15 3/8 x 1 in.).

The dimensions given in the diagram have to be adhered to. An extension of the table top is only possible on the side opposite to the motor.

The ideal height of the table for this machine is 565 mm (approx. 22 in.).

Dimensions in mm (approximation in inches).

## PREPARING THE EMCO - REX B 20 FOR OPERATION

Fig. 1

Fig. 2

Fig. 3

Fig. 4

The Combined Surfacing and Thicknessing Machine EMCO - REX B 20 is delivered assembled, ready for erection and requires only the following additions to make it ready for operation:

- A) Mounting the motor
- B) Mounting the thicknesser-setting units
- C) Mounting the cutter-guard
- D) Mounting the fence unit
- E) Electrical connection

### A) Mounting the Motor

1. Unpack the machine and fasten with 4 hexagon bolts on to the assembled machine stand (Fig.1).
2. Take the motor from its wrappings and prepare as shown in Fig.2.
  - a) Mount the flat-belt tensioning pulley (Fig.2, No.1) in the position shown with the Spanner SW 17.
  - b) Place the flat belt (Fig.2, No.3) on the belt pulley (at the back of No.2).

**IMPORTANT !** In the case of a.c. motors you have to take care that the working capacitor is not damaged when the motor is mounted.

- c) Place the supplied motor fastening screws on the feed table (Fig.1, No.1).
3. Remove the gearing cover (Fig.1, No.2 and 3) after the 3 flat head screws have been unscrewed.
4. Place the toothed belt on to the toothed-belt pulley of the cutter spindle (Fig.3, No.1 and 2).
5. Flange connection of the motor:  
Take the flat belt which has already been placed on the pulley with your right hand and connect it under the tensioning pulley to the motor housing (Fig.4, No.3).  
Now the motor with its toothed-belt pulley is placed on the suspended toothed belt (Fig.4, No.1).  
Then the motor is fastened (for the time being without a spanner — Fig.4, No.2) above the motor switch by means of the prepared hexagon bolt and circlip.
6. After the flat belt has been placed on the pulley (Fig.4, No.4) the remaining motor fastening screws are screwed in. Please make sure that the toothed belt is properly tightened, i.e. the motor has to be pressed down as far as the stop and fastened with 3 hexagon bolts and spanner SW 17.

Fig. 5

Fig. 6

Fig. 7

Diagram A

7. The tensioning pulley which has already been mounted, is now turned down as shown in Fig. 5, so that the flat belt on the opposite side cannot be raised more than 6 mm (approx. 1/4 in.). But on no account must the tensioning roll rest on the belt pulley (Fig.5, No. 2).

8. Refit the gearing cover to the machine housing.

9. Applies only to single-phase a.c. motors

With a.c. motors the operating capacitor is mounted on the machine stand (Fig. 6, No.1).

A capacitor plate and 2 flat head screws M 5x8 are supplied with the capacitor.

The plate is fastened to the capacitor with nut and washer with the Spanner SW 19. Subsequently the capacitor is fixed on the inner side of the machine stand with the two flat head screws (Fig. 6). If a self-built worktable is used, the capacitor has to be mounted at a conveniently protected point of the stand.

10. If the flanged motor was not purchased from us, the following points have to be observed:

A threaded hole (M 6) has to be made into the motor shaft on the face side of the motor. The motor belt pulley pressed on to it by you has to be fastened with the cup wheel and socket head screw (M 6x12 DIN 912) (see Fig. 2).

The wiring diagrams on page 16 apply only to motors supplied by us.

### B) Mounting the Thicknesser-Setting Unit

Remove the end plug (Fig. 7, No. 1) and screw the clamping bolt (Fig. 7, No. 2) into the threaded hole in the side.

### C) Mounting the Cutter Guard

As you can see from Diagram A, the cutter-guard No. 1 is mounted with the grub screw M 5x35 on the bearing cover of the motor shaft.

If your machine is equipped with the SUVA-guard it has to be mounted instead of the normal cutter guard at the side of the planer table (page 12, Fig.8).

### D) Mounting the Fence Unit

The fence unit, diagram A, No. 2, is mounted with 2 socket head screws on the delivery table (Fig. 4, No. 5).

## E) Connecting a Two or Three-Pin Plug, Depending on the Type of Motor Used

In view of the varying types of plug sockets, the EMCO - REX is supplied with a cable without plug.

Only earthed plugs must be used !

The drive of the machine is effected by built-in flanged motor of single or three-phase a.c. type, and its transmitted directly to the cutter spindle by means of a toothed belt.

If a single-phase motor is used, the cable is connected to a standard commercial earthed plug (the yellow/green lead is the earth wire and has to be connected to the earth contact of the plug) which must be protected with at least a 15 amp. fuse. If a three-phase a.c. motor is used, the cable can be directly connected to a distributor box or to a three-pin earthed plug (the yellow/green lead is the earth wire). After connection the machine should be given a trial run to see, whether the direction of motor rotation is correct. If it is not, it has to be reversed by changing two phases in the plug or in the distributor box.

## SURFACING WITH THE EMCO - REX B 20

- Technical data:
- a) Diameter of cutter spindle 55 mm (approx. 2 5/32 in.) with 2 straight-edge knives 25 x 3 x 260 mm (approx. 1 x 1/8 x 10 1/4 in.).
  - b) Diameter of cutting circle 60 mm (approx. 2 3/8 in.).
  - c) Spindle speed 6700 rev/min.
  - d) Cutting speed 21 m/sec (approx. 4150 ft/min.).
  - e) Surfacing width 260 mm (approx. 10 1/4 in.).
  - f) Maximum depth of cut 3 mm (approx. 1/8 in.).

Diagram B

The surfacing machine is used for planing boards and squared timber, for facing the narrow side of boards and for jointing. The knives are set so that they accurately correspond with the height of the delivery table.

If the planer table is lowered by the distance "a", as shown in Diagram B, the depth of cut equals this distance "a".

## CORRECT PROCEDURE FOR SURFACING

Diagram C

The planer table is adjusted by means of the hand grip shown in Diagram C, No. 1. The depth of cut is shown on a laterally mounted scale.

The average depth of cut for which the machine is set is 1 mm = approx. 3/64 in. (maximum 3 mm = approx. 1/8 in.) because at this depth of cut the finish of the planed surface is considerably better than say with a cut of 3 mm (approx. 1/8 in.).

For planing, the workpiece is placed on the feed table, pressed down with both hands and slowly pushed against the cutter spindle. As soon as the workpiece has passed over the cutter spindle, it has to be pressed with one hand against the delivery table while the other hand continues to press the workpiece against the cutter spindle. It is always the hollow side of the board which must be planed (Diagram C). If the board were to be placed on the table

Diagram D

with its curved side, it would be impossible to pass it evenly over the cutter spindle.

For planing the narrow side of a board, the fence is set at right angles with the table surface.

Now the planed surface of the board is pressed against the fence and under even pressure pushed over the cutter spindle (Diagram D).

The cutter spindle has to be covered as far as possible with the cutter guard.

Small workpieces should be planed with the aid of a self-built feeding device to prevent accidents to the hands. The underside of the feeding device can be made slip-resistant by covering it with sanding paper (Diagram E).

Diagram E

The length stop of the planer is laterally and vertically adjustable and it can be turned sideways in both directions through up to  $45^\circ$  (Diagram F). Hence it is possible also to plane the narrow edges of boards. The lateral adjustability is, therefore, of particular advantage because the cutting edges of the straight-edge knives can be used along their entire length. If for planing the narrow edges the stop would always be in the same position, the knives would blunt much quicker at this point.

Diagram F

## PREVENTING ACCIDENTS DURING SURFACING

1. The cutter spindle has to be covered as far as possible by means of the cutter-guard. This is particularly important when small workpieces have to be jointed or planed.
2. Only sharp planing knives should be used. This greatly reduces the kick-back danger.
3. For planing small dimensioned (thin) workpieces it is essential that a feeding device is used.
4. The workpieces have to be pressed on to the worktable with the ball of the thumb, not with the fingers.
5. Piled-up wood chips have to be removed with a board, or they have to be blown off the planing and thickening table before the workpiece is placed in the machine.

## SUVA - GUARD

Fig. 8

### Mounting:

The SUVA-guard is screwed to the side of the planer table with 2 socket head cap screws M 6x20 DIN 912.

### Operation:

By raising the lever (Fig. 8, No. 1) the guard can be removed from the cutter spindle.

This is necessary:

1. When surfacing a board (setting the board thickness).
2. When thicknessing, in order to ensure satisfactory chip removal.

For facing the narrow side of a board, the SUVA-guard is moved laterally according to the board thickness and placed on the planer table.

If workpieces have to be surfaced which are wider than the planer table, the knurled nut "b" is loosened and the guard turned away or removed from the planer table altogether.

## THICKNESSING WITH THE EMCO - REX B 20

### Technical data:

- a) Thicknessing capacity 130 x 250 mm (approx. 5 1/8 x 9 7/8 in.).
- b) Table length 440 mm (approx. 17 5/16 in.).
- c) Maximum depth of cut 3 mm (approx. 1/8 in.).
- d) Automatic feed 6.2 m/min (approx. 20 ft 4 in./min).
- e) 2 straight-edge knives 25 x 3 x 260 mm (approx. 1 x 1/8 x 10 1/4 in.).
- f) Diameter of cutting circle 60 mm (approx. 2 3/8 in.).
- g) Spindle speed 6700 rev/min.
- h) Cutting speed 21 m/sec (approx. 4150 ft/min).

With the thicknessing machine boards and planks can be planed parallel to a desired thickness.

The automatic feed and the multi-plate kick-back guard ensure a continuous and safe operation of the machine.

The required thickness of the workpiece is set by means of the handwheel (Fig. 9, No.1) and setting scale (Fig. 9, No. 2). Subsequently the thicknesser table is locked with a clamping screw (Fig. 9, No. 3). The automatic feed operated by the flanged motor is transmitted to the transport and grooved roller respectively by way of flat belts (safty factor in case of overloads), a gear-wheel and chain wheels with simple and roller chains.

Fig. 9

## CORRECT PROCEDURE FOR THICKENING

1. Prior to thickening, every workpiece must be planed on one side. This is absolutely essential to ensure that the surfaces become even.
2. The planed board is placed with the planed side on to the thickener table and moved forward as far as the grooved roller.
3. Workpiece of uneven thickness are always inserted with the thicker end first to prevent jamming the machine.
4. If the maximum depth of cut of 3 mm (approx. 1/8 in.) is exceeded, the workpiece cannot be fed into the machine.
5. Hence greater depths of cut can only be obtained by several machine passages.
6. If the workpiece jams during its passage through the machine (due to an excessive depth of cut) the thickener table has to be lowered by about 1 mm (approx. 3/64 in.) by means of the handwheel and the workpiece pushed forward again.
7. If narrow workpieces (fillets) have to be machined, they must not always be placed on the same point of the table so that the entire length of the knife is utilized.
8. The thickener table should at intervals be cleaned to remove chips and other contaminating deposits.
9. If after some time a workpiece should become stuck due to excessive friction, the thickener table has become tacky through resin accumulations (especially if fir wood and others have been worked). In this case the table must be cleaned with a turpentine-soaked rag. After that the table surface has to be wiped dry and rubbed with paraffin. The table must not be treated with oil as the workpieces would absorb the oil and become unfit for gluing, staining and varnishing.
10. If very thin (less than 5 mm = approx. 13/64 in.), small boards have to be surfaced, they should be placed on a planed board which is about 20 mm (approx. 3/4 in.) thick and be passed through the machine together.

## PREVENTING ACCIDENTS DURING THICKENING

Diagram G

1. The EMCO - REX B 20 Thickening Machine is provided with 16 kick-back plates (fingers) which are spaced across the entire width of the table to prevent the workpieces from recoiling (Diagram G).

- 1 - Kick-back guard
- 2 - Grooved roller
- 3 - Workpiece
- 4 - Cutter spindle
- 5 - Transporting roller

If workpieces of different thicknesses are planed simultaneously it could happen that the thinner pieces recoil. This is prevented by the multi-plate kick-back guard.

2. The cutter spindle is covered with the linked covers of the cutter-guard.
3. Care must be taken that any nails or other foreign bodies are removed from the workpieces prior to thickening.
4. Workpieces which are shorter than 130 mm (approx. 5 1/8 in.) must not be fed into the machine because the transporting roller is unable to safely guide them through the machine.
5. After the work has been completed, the thickener table has to be lowered into the bottommost position and the chips removed.

## HANDLING THE WORKPIECES

Boards are mostly placed upended on the floor so that sand and small stones become embedded in the ends which can cause damage to the planing knives. You can protect your cutters by having the rough ends of the boards cut off prior to planing.

To ensure that a perfect surface is obtained, it is important that for surfacing and thickening the workpieces are fed into the machine in the direction of the grain (Diagram H).

## SHARPENING (HONING) THE STRAIGHT-EDGE KNIVES

Diagram J

If apart from the chips much wood dust is generated during planing this is an indication that the knives are no longer sufficiently sharp. In this case the straight-edge knives can, without dismantling them, be sharpened in the machine with a fine-grain whetstone (Diagram J, No. 1) (size approx. 25 x 15 x 100 mm = approx. 1 x 5/8 x 4 in.). The whetstone is oiled and placed against the cutter spindle as shown in Diagram J. In this position the stone is evenly moved forward and backward along the entire length of the knife under moderate pressure until the knife is sharp.

## CHANGING AND SETTING THE STRAIGHT-EDGE KNIVES

After the machine has been used for some time, the knives may become notchy, due to foreign bodies in the workpieces (sand, small stones etc.). These notches will show in the machined workpieces in the form of raised longitudinal ribs. Straight-edge knives which are notchy or blunt, and are unsuitable for further sharpening with the whetstone, must be dismantled and ground outside the machine.

It is very advantageous if you have a spare set of knives which you can use until the first set is available again.

### 1. Dismantling the straight-edge knives

The feed table is lowered into its bottommost position by means of the handle so that the fixing screws of the knives can be easily reached.

Now the screws of one of the knives are removed with the socket key, and the backing plate with the straight-edge knife taken out. After turning the cutter spindle a little further, the second knife is removed in the same way. The grooves of the cutter spindle, the backing plates and the straight-edge knives have to be thoroughly cleaned to remove all wood dust.

### 2. Installation of the ground straight-edge knives and setting by means of a surfaced wood fillet

One of the knives is inserted together with the backing plate into one of the grooves of the cutter spindle, and temporarily held by the 4 socket screws. Now a ruler is held upended on the delivery table and the cutter spindle is turned so that the knife reaches its highest point. In this position both ends of the cutting edge of the knife must just touch the ruler. If they do not touch it, the knife, with slightly tightened screws, must be adjusted with both its laterally projecting ends until it reaches the level of the ruler. In this position the screws are tightened.

### 3. Setting the straight-edge knives with the Setting Gauge Ref. 6275

For this purpose the straight-edge knives are inserted into the cutter spindle and temporarily fixed. The setting gauge (Diagram K, No. 1) is placed on the side of the delivery table as shown in Diagram K. The cutter spindle is turned until the knife is parallel with the setting gauge. A correctly set knife must with both its ends fully bear against the setting gauge. Care must be taken that the setting gauge rests evenly on the delivery table.

### MAINTENANCE OF THE MACHINE

The machine is maintenance-free and therefore not subject to any lubrication instructions.

In spite of that, the machine parts should at certain intervals be cleaned of adhering wood dust and chips.
